Ransomware

Ransomware is a type of malicious software from cryptovirology that threatens to publish the victim's data or perpetually block access to it unless a ransom is paid. While some simple ransoms may lock the system in a way which is not difficult for a knowledgeable person to reverse, more advanced malware uses a technique called cryptoviral extortion, in which it encrypts the victim's files, making them inaccessible, and demands a ransom payment to decrypt them. In a properly implemented cryptoviral extortion attack, recovering the files without the decryption key is an intractable problem — and difficult to trace digital currencies such as Ukash and Bitcoin are used for the ransoms,

making tracing difficult. Recent Ransomware attack in 2017 has caused a stir in the world as the attack caused many of the internet connected devices to not work and companies spent a large amount to recover from these attacks.

Ransomware attacks are typically carried out using a Trojan that is disguised as a legitimate file that the user is tricked into downloading or opening when it arrives as an e-mail attachment. However, one high-profile example, the "WannaCry worm", traveled automatically between computers without user interaction.

Starting from around 2012 the use of ransomware scams has grown internationally. In June 2013, vendor McAfee released data showing that it had collected more samples than previous year.
